Finally, no "basic stress analysis calculations" guide would be complete without explaining how to calculate the max stress based on a selected safety factor. The safety factor is given by the formula " $f_s = Y_s / D_s$ ", with Y_s being the yield strength of the material and D_s the design stress, both defined during the experimental phase.

Note 1. 1. PSC Stresses for a moving load are generated only when 'Normal + Concurrent Force' of Frame is checked in Analysis > Moving Load Analysis Control Data. 2. If Tendon Prestress Load is not applied after a tendon is inputted, or if a tendon is not applied during construction stages, the tendon is not reflected in the analysis, unlike in the PSC design.

Consider five designers working on a piping layout with one stress engineer validating their layouts. The engineer becomes the bottleneck; s/he simply cannot sign off on all the stress projects in a timely manner, what with having to do a "back-and-forth" design review with the five designers to first arrive at an acceptable layout before delving into the analysis details.
